Lay summary
Friction caused by blood flowing across cells that line blood vessels (endothelial cells), activates sensors of mechanical force. This produces nitric oxide (NO) which widens placental blood vessels, enabling more blood flow to the baby. We sought to determine whether the mechanical sensor, Piezo1, is important for NO production in fetoplacental endothelial cells (FpECs), and whether the steps in this pathway are different in small for gestational age (SGA) babies, where placental blood flow is often altered.

We showed that in healthy FpECs, flow increased NO signalling. We suggest that in SGA babies, FpECs have an increase in background levels of NO signalling, suggestive of a compensatory drive. Treating healthy and SGA cells with a Piezo1 chemical activator, Yoda1, upregulated NO signalling. This shows that Piezo1 is linked to NO, and that in SGA, FpECs have the capacity to further increase NO.

Further research will establish whether Piezo1 enhancement leads to increased blood flow in the placenta. If so, Piezo1 could be a new target for developing treatments to prevent poor growth of babies in the womb.

Lay summary

Friction caused by blood flowing across cells that line blood vessels (endothelial cells), activates sensors of mechanical force. This produces nitric oxide (NO) which widens placental blood vessels, enabling more blood flow to the baby. We sought to determine whether the mechanical sensor, Piezo1, is important for NO production in fetoplacental endothelial cells (FpECs), and whether the steps in this pathway are different in small for gestational age (SGA) babies, where placental blood flow is often altered.

We showed that in healthy FpECs, flow increased NO signalling. We suggest that in SGA babies, FpECs have an increase in baseline levels of NO signalling, suggestive of a compensatory drive. Treating healthy and SGA cells with a Piezo1 chemical activator, Yoda1, upregulated NO signalling. This shows that Piezo1 is linked to NO, and that in SGA, FpECs have the capacity to further increase NO.

Summary: Further research will establish whether Piezo1 enhancement leads to increased blood flow in the placenta. If so, Piezo1 could be a new target for developing treatments to prevent poor growth of babies in the womb.

Research

Babies are born small for gestational age (SGA) in up to 10% of pregnancies, which can have both immediate and long-term clinical consequences (Audette & Kingdom, 2018). The condition is multifactorial but is commonly associated with altered blood flow within the placental circulation.

Fetoplacental endothelial cells (FpECs) are constantly exposed to fluid shear stress (FSS) by blood flow. This FSS is the most powerful stimulus for the production of nitric oxide (NO) via
endothelial NO synthase (eNOS), which is well known to induce placental vasodilatation (Learmont & Poston, 1996; Sprague et al., 2010). Detailed knowledge of the mechanism by which FSS leads to NO synthesis in humans is lacking.

Our group investigated the FSS-sensor, Piezo1. This Ca\textsuperscript{2+}-permeable ion channel is increasingly recognised as important for vascular adaptation in multiple body systems. We demonstrated a reduction in FSS-evoked eNOS in commercially sourced pooled human umbilical vein endothelial cells (HUVECs) after Piezo1 silencing, suggesting that Piezo1 had a regulatory role through NO (Li et al., 2014). We showed that Piezo1 was consistently expressed in FpECs cultured from human placentas, and activation with the small molecule channel agonist, Yoda1, increased intracellular Ca\textsuperscript{2+} (Morley et al., 2018).

We sought to determine whether Piezo1 activity led to NO signalling, and if there were differences between healthy placentas and those where the baby had been SGA. FpECs were cultured from placentas of patients undergoing elective caesarean section at Leeds Teaching Hospitals NHS Trust as previously described (Morley et al., 2018). Patients were recruited as either SGA or appropriately grown for gestational age (AGA). SGA was defined as birthweight <10\textsuperscript{th} percentile on UK-World Health Organisation Growth Charts.

FpECs from AGA samples exposed to FSS were probed with antibody to phosphorylation (p) at serine site 11777 (S1177) in endothelial NO synthase (eNOS), which is linked to eNOS activation. When compared to the static control, FpECs exposed to FSS had greater p-eNOS relative to total eNOS (teNOS, \textit{p} \textless 0.018, fig 1A, B).

Basal levels of p-eNOS were compared between AGA and SGA samples. This demonstrated a significant increase in p-eNOS in SGA lysates, when normalised to teNOS (\textit{p} 0.0007, fig 1C, D). There was no evidence of a difference in teNOS in the SGA samples versus AGA, when normalised to \(\beta\)-actin (relative to AGA, \textit{p} 0.34, fig 1E).

Yoda1 was applied to FpECs, and lysates probed with anti-S1177 p-eNOS and anti-eNOS antibodies as above. In AGA FpECs, Yoda1 increased p-eNOS versus vehicle control (DMSO) relative to teNOS (\textit{p} 0.031, fig 1F, G). In SGA FpECs, Yoda1 treatment also significantly increased p-eNOS compared to vehicle control (normalised to teNOS, \textit{p} 0.0003, and fig 1F, G). The intensity of p-eNOS induced by Yoda1 application did not significantly differ between the AGA and SGA groups, when normalized to either teNOS or \(\beta\)-actin (\textit{p} 0.811 and \textit{p} 0.752, fig 1H, I, respectively). In addition, there was no evidence of a difference in teNOS between the groups after Yoda1 treatment (\textit{p} 0.603, fig 1J).
These findings demonstrate coupling between Piezo1 and p-eNOS in FpECs. We show that Yoda1 phosphorylates the S1177 regulatory site on eNOS in the fetoplacental endothelial cells in both AGA and SGA placentas, mimicking flow-induced p-eNOS. We propose that basal p-eNOS undergoes upregulation in SGA. The basal NO signalling pathway is not saturated in these cells, however, as Yoda1 led to further enhancement of p-eNOS. This raises the question of whether Piezo1 agonism could be a novel intervention for treatment SGA, by promoting production of the key vasodilator, NO.

Figure 1. SGA FpECs show increased basal eNOS S1177 phosphorylation, and Yoda1 increases p-eNOS in AGA and SGA FpECs. (A) Representative Western blot (Wb) labelled with anti-phospho(p)-eNOS (S1177) and anti-eNOS antibodies for AGA FpECs exposed to 10 dyn/cm² FSS on an orbital shaker (FSS) or not (Static, St). (B) Quantification of data of the type exemplified in (A), showing mean ± S.D. for p-eNOS intensity relative to total eNOS (teNOS), normalised to static condition (n=3). (C) Representative Wb labelled with anti-p-eNOS (S1177), anti-eNOS antibodies and anti-β-actin for FpECs isolated from AGA or SGA samples (n=3/4, N=2 replicates, respectively). (D-E) Quantification of data of the type exemplified in (C), showing mean ± S.D. for p-eNOS intensity relative to teNOS (D) or teNOS intensity relative to β-actin (E) normalised to AGA. (F) Representative Wb labelled with anti-p-eNOS (S1177), anti-eNOS and anti-β-actin for FpECs isolated from AGA or SGA samples and exposed to 2 µM Yoda1 for 1 min or vehicle (Veh) control (DMSO). (G-H) Quantification of data of the type exemplified in (F), showing mean ± S.D. for p-eNOS intensity relative to teNOS normalised to AGA Veh condition (G) or to respective Veh condition (H). (I) teNOS intensity relative to β-actin normalised to AGA Veh (n=4 each group). Superimposed dots are the individual underlying data values for each individual experiment. *p<0.05, ***p<0.001 vs. stated condition. Statistical significance was evaluated using two-way RM Matched ANOVA followed by Šidák’s posthoc test for multiple comparisons using Welch’s t-test.
